Machine learning - NLP Analysis Reviews

Part 1 - Business Problem Classifying Topics in Amazon Product Reviews

Objective: Amazon has a large volume of customer reviews for various products. These reviews contain valuable information about customer experiences, which can be useful for improving product search and providing better recommendations. However, the massive volume of data makes it challenging to manually extract the main topics from the reviews. The goal is to create a Topic Modeling model that automatically identifies and classifies the main topics within the product reviews.

Project Objectives:

1. Dataset Exploration and Data Cleaning:

- · Remove null and inconsistent values.
- o Check for duplicates in the data.
- · Perform text preprocessing, such as removing stopwords, tokenization, and applying stemming or lemmatization.

2. Topic Modeling:

- Apply *Topic Modeling* techniques such as *Latent Dirichlet Allocation (LDA)* or *Non-Negative Matrix Factorization (NMF)* to identify the main topics in the reviews.
- Test different numbers of topics and evaluate the quality of the identified topics.
- o Identify the most representative words for each topic.

3. Topic Classification:

• Once the topics are identified, classify the reviews into different categories to facilitate search.

4. Evaluation:

- o Assess the coherence of the generated topics using topic coherence metrics.
- Interpret and label the topics meaningfully to improve visualization and search.

5. Results and Impact:

- Provide a set of categories or topics that help users quickly filter reviews based on discussed themes (product quality, shipping, customer support, etc.).
- o Implement the model in a way that it can be applied to new data automatically.

Success Indicators:

import numpy as np
import pandas

- · Topic coherence (using topic coherence metrics).
- · Quality of the review categorization.
- · Ease of navigation through the generated topics.

Here, we performed text preprocessing, which included several important steps. First, we carried out **text cleaning**, removing special characters such as punctuation, symbols, and irrelevant numbers to ensure that the model would not be influenced by noise. Additionally, we standardized the text by applying techniques such as converting to lowercase and removing extra spaces.

The second part of the preprocessing involved **text tokenization**, where the content was segmented into individual words (tokens). This step is crucial for further analysis, allowing each word to be handled separately rather than treating the text as a single block. Tokenization also facilitates the conversion of words into numerical representations, a necessary step for training machine learning and deep learning models.

If needed, other preprocessing techniques can be applied, such as removing stopwords (common words that add little meaning, like "the", "and", "of"), stemming or lemmatization (reducing words to their root forms), and the creation of n-grams to capture word combinations.

Part 4.1 - Sentiment Analysis with Vader

```
from vaderSentiment.vaderSentiment import SentimentIntensityAnalyzer
# Create an instance of SentimentIntensityAnalyzer, which is part of the VADER sentiment analysis tool.
analyzer = SentimentIntensityAnalyzer()
# Function to apply VADER sentiment analysis to each review.
# The function takes in a 'review' (text) and returns the polarity scores, which include
# 'compound', 'positive', 'negative', and 'neutral' sentiment values.
def get_sentiment(review):
    return analyzer.polarity_scores(review)
# Apply the 'get_sentiment' function to each entry in the 'Cleaned_Review' column.
# Store the resulting sentiment scores (dictionary) in a new column 'vader_scores'.
df['vader_scores'] = df['Cleaned_Review'].apply(get_sentiment)
# Extract the 'compound' score from the 'vader_scores' dictionary for each review.
# The 'compound' score is a normalized score ranging from -1 (most negative) to +1 (most positive),
# summarizing the overall sentiment of the text.
df['compound'] = df['vader_scores'].apply(lambda score_dict: score_dict['compound'])
# Function to classify the sentiment based on the 'compound' score.
# Scores >= 0.05 are classified as 'Positive', <= -0.05 as 'Negative', and anything in between as 'Neutral'.
def classify_sentiment(compound_score):
    if compound score >= 0.05:
```

```
return 'Positive'
    elif compound score <= -0.05:
        return 'Negative'
    else:
        return 'Neutral'
# Apply the 'classify sentiment' function to the 'compound' score to get the overall sentiment
# classification (Positive, Negative, or Neutral) for each review.
df['sentiment'] = df['compound'].apply(classify_sentiment)
# Display the first few rows of the DataFrame, showing the cleaned review text,
# the 'compound' sentiment score, and the classified 'sentiment'.
print(df[['Cleaned_Review', 'compound', 'sentiment']].head(10))

```

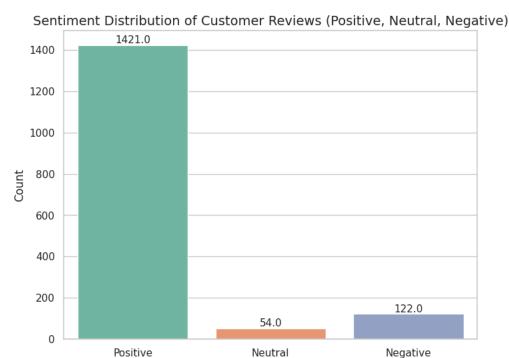

In this script, we apply the VADER (Valence Aware Dictionary and sEntiment Reasoner) sentiment analysis tool to classify the sentiment of textual reviews. VADER is a popular rule-based model used to analyze the sentiment expressed in text, specifically designed to handle social media, but applicable to any type of textual data.

- Sentiment Analysis with VADER: We start by initializing an instance of SentimentIntensityAnalyzer, which computes the polarity of a given text. VADER calculates four sentiment scores for each review: positive, negative, neutral, and a compound score. The compound score represents an overall sentiment, normalized between -1 (extremely negative) to +1 (extremely positive).
- Extracting the Compound Score: After applying VADER to each review in the Cleaned_Review column, we store the results in a new column vader_scores. From this dictionary, we specifically extract the compound score, which simplifies the task of classifying the overall sentiment into 'Positive', 'Negative', or 'Neutral' based on defined thresholds.
- Classifying Sentiments: The classify_sentiment function uses the compound score to categorize the sentiment. A score greater than or equal to 0.05 indicates a positive sentiment, a score less than or equal to -0.05 indicates a negative sentiment, and anything in between is considered neutral. This classification helps in understanding the emotional tone conveyed in the review text.
- Final Output: After applying the sentiment classification, the DataFrame now contains columns for the original cleaned review text, the compound score, and the final sentiment label. This allows for easy interpretation of both the numerical sentiment scores and their respective categories (Positive, Neutral, or Negative). We then display the first few entries to visualize the results.

Overall, this script demonstrates a simple and effective way to perform sentiment analysis on text data using VADER, allowing for automated categorization of emotional tone in customer reviews, feedback, or any other form of written text."

Part 5 - Exploratory data analysis

₹

Analysis

1. **Positive Sentiment Dominance**: - The overwhelming majority of reviews are classified as **Positive** (1,421 counts). This suggests that customers are generally satisfied or expressing favorable opinions in the reviews.

Sentiment

- 2. **Neutral Sentiment**: There is a significantly lower number of reviews classified as **Neutral** (54 counts). This means that few reviews are neither strongly positive nor negative, showing a lack of middle-ground feedback.
- 3. **Negative Sentiment**: A small portion of reviews is classified as **Negative** (122 counts). While fewer than positive reviews, this indicates that some customers are sharing dissatisfaction or negative experiences.
- 4. **Visual Representation**: The **bar plot** clearly highlights the disproportionate distribution of sentiments, where **positive reviews far outnumber** both negative and neutral sentiments.
 - · Labeling is well done, with the exact count numbers annotated on top of each bar, allowing for easy understanding of the data.
- 5. **Improvements in Balance**: If the dataset aims to represent a balanced sentiment analysis, it might be necessary to gather or balance more negative or neutral reviews to avoid the positive sentiment dominance. Alternatively, such an imbalance could be a reflection of a generally positive customer experience.

Most Common Words in Neutral Reviews

Frequency

Section A) Machine learning models

Part 6 - Target column split and test

The **TfidfVectorizer** is used to convert the textual data into numerical features suitable for machine learning models. Specifically, TF-IDF (Term Frequency-Inverse Document Frequency) helps quantify the importance of each word in a document relative to a corpus of documents. Here's why it's being used:

1. Convert Text to Numeric Format:

 Machine learning models work with numerical data, not raw text. The TfidfVectorizer transforms the cleaned text data (in this case, the Cleaned_Review column) into a sparse matrix of numerical features. Each word in the reviews becomes a feature that can be used by the model for classification.

2. Capturing Importance of Words:

The TF-IDF mechanism works by considering both the frequency of a word in a document (Term Frequency, or TF) and how unique that
word is across the entire set of documents (Inverse Document Frequency, or IDF). This way, commonly used words like "the" or "and"
(which don't carry much meaning in sentiment analysis) get lower scores, while more important, topic-specific words receive higher
scores.

3. Avoiding Overfitting to Common Words:

• By using TF-IDF instead of simple word counts, you prevent the model from giving too much importance to frequently occurring but **less** meaningful words (like "the" or "is"). Instead, words that appear in fewer documents but have more significance (like "excellent" or "bad") are given higher weights.

4. Reducing Dimensionality:

• The parameter max_features=5000 limits the vectorizer to the top 5,000 most important words (features). This prevents the model from being overwhelmed by too many features, especially if there are many unique words across the reviews, which helps reduce computational cost and potentially improves model performance.

5. Better Representation for Sentiment Analysis:

• In sentiment analysis, certain words carry more weight in determining whether a review is positive, negative, or neutral. The **TF-IDF** approach captures this and allows your model to learn the relationships between words and sentiment categories more effectively than simple bag-of-words approaches.

6. Sparse Representation:

• The resulting x is a **sparse matrix**, meaning that only non-zero values (relevant words) are stored, which saves memory and speeds up the computation, especially in large datasets where many words do not appear in every document.

In summary, **TfidfVectorizer** helps convert the text data into numerical features while highlighting the most important and relevant words, thereby improving the model's ability to understand and classify text data. It's commonly used for tasks like **text classification**, **sentiment analysis**, **and topic modeling**.

```
# Visualizing data x X.shape

→ (1597, 5000)

# Viewing y data y.shape

→ (1597,)
```

Here, we performed the division of the variables into features and the target variable. First, we separated the independent variables, which are the features used for predictive modeling. These features are the input data that the model will use to learn patterns and make predictions. Next, we isolated the dependent variable, or the target variable, which is the value we aim to predict. This process is crucial for building and training the model, ensuring that the features are correctly identified and that the model can learn the relationship between these features and the target variable. By properly dividing the data, we enhance the model's ability to accurately predict outcomes based on the given inputs

Part 6.1 - Engineering features

```
# Import the LabelEncoder class from sklearn, which is used to convert categorical labels to numeric values
from sklearn.preprocessing import LabelEncoder

# Initialize the LabelEncoder instance
le = LabelEncoder()

# Apply LabelEncoder to the target variable 'y', which contains categorical sentiment labels
# The fit_transform() method encodes the labels (e.g., 'Positive', 'Neutral', 'Negative') into numeric values (e.g., 0, 1, 2)
y = le.fit_transform(y)

# The 'le' object now contains the mapping between the original labels and the numeric values
le
```

```
LabelEncoder()
```

Here, we conducted the training of the model using a train-test split. We adopted an 80/20 division, where 80% of the data was used for training and the remaining 20% was reserved for testing. This procedure is crucial for accurately evaluating the model's performance. The training set allows the model to learn patterns and relationships within the data, while the test set, which the model has not seen during training, is used to validate its ability to generalize and predict new data. Additionally, this approach helps identify and mitigate issues such as overfitting, ensuring that the model not only memorizes the training data but also performs well on unseen data.

```
# Convert your TF-IDF sparse matrix to a dense matrix
X_train_dense = X_train.toarray()
X_test_dense = X_test.toarray()
```

- Here, we conducted the training of the model using a train-test split. We adopted an 80/20 division, where 80% of the data was used for training and the remaining 20% was reserved for testing. This procedure is crucial for accurately evaluating the model's performance.
- The training set allows the model to learn patterns and relationships within the data, while the test set, which the model has not seen during training, is used to validate its ability to generalize and predict new data.
- Additionally, this approach helps identify and mitigate issues such as overfitting, ensuring that the model not only memorizes the training

Model 7: LGBMClassifier
Training Accuracy: 0.9969
Testing Accuracy: 0.9219
Model 8: KNeighborsClassifier
Training Accuracy: 0.9076
Testing Accuracy: 0.8938
Model 9: GradientBoostingClassifier
Training Accuracy: 0.9984
Testing Accuracy: 0.9313
```

1. Model 1: GaussianNB

Training Accuracy: 96.63%Testing Accuracy: 88.44%

Analysis: Gaussian Naive Bayes performs well on the training data with relatively high accuracy, but there's a noticeable drop when
evaluated on the testing data. This indicates that the model is slightly overfitting to the training data but still generalizes reasonably well.

2. Model 2: DecisionTreeClassifier

• Training Accuracy: 100%

• Testing Accuracy: 88.75%

Analysis: The decision tree model has perfect accuracy on the training set, which is often a sign of overfitting—the model learns the noise
and specific patterns in the training data. Despite this, the testing accuracy is decent but shows a gap between training and testing,
confirming overfitting.

3. Model 3: RandomForestClassifier

• Training Accuracy: 100%

Testing Accuracy: 91.87%

Analysis: Random Forest also overfits on the training data with perfect accuracy, but it generalizes much better on the testing set, with
one of the highest testing accuracies. Random Forest's ability to reduce variance likely contributes to its good generalization, though the
perfect training accuracy still hints at overfitting.

4. Model 4: LogisticRegression

• Training Accuracy: 91.78%

Testing Accuracy: 90.62%

Analysis: Logistic Regression shows a healthy balance between training and testing accuracies. Both are close, indicating that the model
generalizes well without overfitting or underfitting. This makes it one of the most balanced models in this comparison.

5. Model 5: AdaBoostClassifier

• Training Accuracy: 90.52%

• Testing Accuracy: 86.88%

 Analysis: AdaBoost has slightly lower accuracy on both training and testing sets compared to other models like RandomForest or Logistic Regression. It does not overfit, but it may not be capturing complex patterns in the data as well as more sophisticated models.

6. Model 6: XGBClassifier

• Training Accuracy: 80.74%

• Testing Accuracy: 78.44%

Analysis: XGBoost shows relatively low accuracy on both training and testing sets. This could indicate underfitting, where the model is
too simplistic or hasn't fully captured the data patterns. There may be potential for tuning hyperparameters to improve performance.

7. Model 7: LGBMClassifier

• Training Accuracy: 99.61%

Testing Accuracy: 91.87%

Analysis: LightGBM has one of the highest testing accuracies, very close to Random Forest and Gradient Boosting. Although the training
accuracy is nearly perfect, the testing accuracy indicates the model generalizes well, making it a strong contender for this task. However,

some warnings during training suggest hyperparameter tuning could further improve its performance.

8. Model 8: KNeighborsClassifier

- Training Accuracy: 90.37%
- Testing Accuracy: 88.75%
- Analysis: K-Nearest Neighbors shows a moderate performance, with similar results on training and testing sets. There's no clear sign of
 overfitting or underfitting, but the model doesn't perform as well as others like Logistic Regression or Random Forest.

9. Model 9: GradientBoostingClassifier

- Training Accuracy: 100%
- Testing Accuracy: 93.13%
- Analysis: Gradient Boosting has the highest testing accuracy of all models, demonstrating excellent generalization. Like other ensemble
 methods (Random Forest, LightGBM), it overfits on the training set but generalizes better on unseen data. Gradient Boosting's strong
 performance makes it a top choice in this comparison.

Summary of Performance:

1. Best Performers:

- o GradientBoostingClassifier (Training: 100%, Testing: 93.13%)
- o LGBMClassifier (Training: 99.61%, Testing: 91.87%)
- o RandomForestClassifier (Training: 100%, Testing: 91.87%)

These models demonstrate strong generalization to the test set while managing high accuracy.

2. Balanced Performers:

 LogisticRegression (Training: 91.78%, Testing: 90.62%) offers a good balance between training and testing accuracy, avoiding overfitting while maintaining solid performance.

3. Potential for Improvement:

- XGBClassifier (Training: 80.74%, Testing: 78.44%) shows signs of underfitting and might benefit from further tuning.
- AdaBoostClassifier and KNeighborsClassifier also lag slightly behind in testing accuracy compared to the top-performing models, but could still be useful depending on the dataset.

Recommendations:

- GradientBoostingClassifier stands out as the top-performing model, with high testing accuracy and robustness.
- LGBMClassifier and RandomForestClassifier also perform very well and could be solid alternatives.
- Logistic Regression provides a well-balanced option, with no signs of overfitting and consistent performance across both datasets.

Part 8.1 - Feature importances

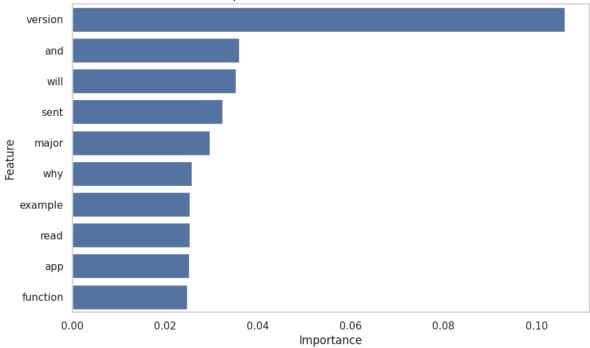

Feature importances refers to the measure of how important each feature is for a machine learning model in making predictions or classifications. In other words, it is a way to quantify the impact or contribution of each feature to the decisions made by the model. In many machine learning algorithms such as decision trees, Random Forest, Gradient Boosting, among others, it is possible to calculate the importance of features during model training.

This is done by observing how each feature influences the decisions made by the model when dividing the data into decision tree nodes or by weighing the features in other model structures.

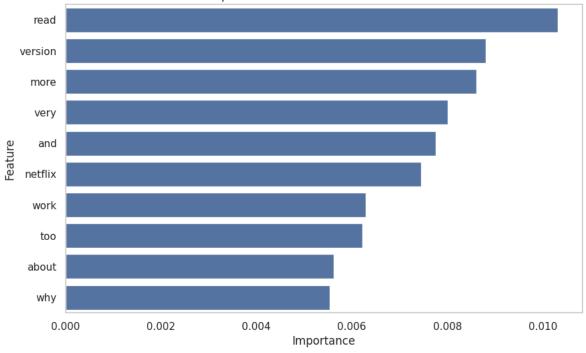

Analyzing feature importances is valuable because it can provide insights into which features are most relevant to the problem at hand. This information can be used to optimize the model, remove irrelevant or redundant features, identify important factors for prediction, and even assist in interpreting the model's results.

```
for model_name, model in models_with_feature_importances:
   # Train model
   model.fit(X_train, y_train)
   # Get importance of features
   if hasattr(model, 'feature_importances_'):
        feature_importances = model.feature_importances_
   else:
        # If the model does not have feature_importances_, continue to the next model
       print(f"{model_name} does not support feature importances.")
   # Create DataFrame for easier viewing
   feature_importances_df = pd.DataFrame({'Feature': feature_names,
                                           'Importance': feature_importances})
   # Sort by importance
   feature_importances_df = feature_importances_df.sort_values(by='Importance', ascending=False)
   # Plot
   plt.figure(figsize=(10, 6))
   sns.barplot(x='Importance', y='Feature', data=feature_importances_df[:10])
   plt.title(f"Top 10 Features - {model_name}")
   plt.xlabel('Importance')
   plt.ylabel('Feature')
   plt.grid(False)
   plt.show()
```

```

Top 10 Features - LGBMClassifier

1. DecisionTreeClassifier:

- Top Feature: "version" has the highest importance, contributing more than 0.10 to the decision process.
- Other Features: Common words like "and", "will", "work", and "sent" also have notable importance, but their contribution is much lower than "version".
- **Observation**: Decision trees often focus on specific features that are highly informative. The high importance of "version" suggests this feature provides significant distinguishing power for the model's predictions.

2. RandomForestClassifier:

- **Top Feature**: "read" emerges as the most important feature, followed by "netflix" and "very". These words have relatively smaller differences in their importance compared to the DecisionTreeClassifier.
- **Observation**: Random Forest spreads the importance across several features, reducing over-reliance on any single word. This leads to a more robust model as it uses multiple important words in combination, resulting in better generalization.

3. XGBClassifier:

- **Top Feature**: Like in the DecisionTreeClassifier, "version" is also the most important feature in the XGBoost model, followed by "sent", "major", and "catcherr".
- **Observation**: XGBoost, similar to DecisionTreeClassifier, tends to focus on key features but combines this with boosting techniques to improve generalization. The top features are more impactful in XGBoost, contributing a significant amount to predictions.

4. LGBMClassifier:

- Top Feature: Surprisingly, "the" is the most important feature in the LightGBM model, followed by other common stopwords like "and", "to", and "is".
- Observation: This is unusual because these stopwords usually have little predictive power. It could suggest the need for further
 preprocessing to remove such words. LightGBM's distributed approach spreads importance across many features, which could explain
 the high importance of generic words.

General Insights:

- Consistency Across Models: Some features, like "version" and "read", are consistently important across different models (e.g.,
 DecisionTreeClassifier, XGBClassifier, RandomForest). This suggests these features are strong indicators of the target variable in your
 data.
- **Stopwords**: The importance of stopwords like "the", "and", "is" in LightGBM suggests potential overfitting or a need for further text preprocessing, such as removing common stopwords.
- Model Differences: While DecisionTreeClassifier and XGBClassifier focus on a few high-importance features, models like RandomForest and LightGBM distribute the importance more evenly, which is typical for ensemble methods aiming to reduce overfitting by combining multiple weak learners.

Recommendations:

- Feature Engineering: Consider improving preprocessing by removing common stopwords like "the" and "and", especially for models like LightGBM that seem to overvalue these words.
- **Hyperparameter Tuning**: The models already show distinct preferences for certain words, but fine-tuning parameters could help enhance performance, especially for models like XGBClassifier and LGBMClassifier that benefit greatly from careful hyperparameter adjustments.

Part 9) Evaluation metrics

```
\hbox{\tt\# Check if the model requires dense data (like $\sf GaussianNB)$}

Testing Accuracy: 0.93125

Confusion matrix for Model 9: GradientBoostingClassifier

Confusion Matrix - Model 9: GradientBoostingClassifier

Model 1: GaussianNB

- True Positive (Positive): 12
- False Negative (Positive predicted as Negative): 19
- True Negative (Negative): 269
- False Positive (Negative predicted as Positive): 11
- **Observation**: GaussianNB struggles with distinguishing the positive class, misclassifying many positive reviews as negative (19 false negatives). However, it performs well in identifying the negative class.

Model 2: DecisionTreeClassifier

- True Positive (Positive): 16
- False Negative (Positive predicted as Negative): 13
- True Negative (Negative): 266
- False Positive (Negative predicted as Positive): 11
- **Observation**: The DecisionTreeClassifier performs better than GaussianNB for the positive class but still has significant false negatives. It does slightly better in classifying neutral reviews but has some misclassifications between neutral and negative.

Model 3: RandomForestClassifier

- True Positive (Positive): 11
- False Negative (Positive predicted as Negative): 20
- True Negative (Negative): 281
- False Positive (Negative predicted as Positive): 0
- Observation: RandomForestClassifier has the highest accuracy in classifying the negative class (no false positives). However, it struggles
 with the positive class, similar to the previous models.

Model 4: LogisticRegression

- True Positive (Positive): 7
- False Negative (Positive predicted as Negative): 24
- True Negative (Negative): 281
- False Positive (Negative predicted as Positive): 0
- **Observation**: LogisticRegression underperforms in the positive class, with a large number of false negatives. Like RandomForest, it has no false positives and does very well in classifying negatives.

Model 5: AdaBoostClassifier

- True Positive (Positive): 1
- False Negative (Positive predicted as Negative): 30
- True Negative (Negative): 273
- False Positive (Negative predicted as Positive): 4
- Observation: AdaBoostClassifier significantly underperforms in the positive class, with the majority of positive reviews being
 misclassified as negative. It does well in classifying negative reviews.

Model 6: XGBClassifier

- True Positive (Positive): 0
- False Negative (Positive predicted as Negative): 31
- True Negative (Negative): 250
- False Positive (Negative predicted as Positive): 26
- Observation: XGBClassifier struggles the most with positive and negative classification, misclassifying all positive reviews as negative. It
 also has a high number of false positives.

Model 7: LGBMClassifier

- True Positive (Positive): 11
- False Negative (Positive predicted as Negative): 20
- True Negative (Negative): 280
- False Positive (Negative predicted as Positive): 0
- Observation: LGBMClassifier performs similarly to RandomForest, with good accuracy in the negative class but struggles with the positive class.

Model 8: KNeighborsClassifier

- True Positive (Positive): 5
- False Negative (Positive predicted as Negative): 26
- True Negative (Negative): 279
- False Positive (Negative predicted as Positive): 2
- **Observation**: KNeighborsClassifier performs poorly in the positive class, similar to other models, with many false negatives. It performs well in the negative class with only a few false positives.

Model 9: GradientBoostingClassifier

- True Positive (Positive): 15
- False Negative (Positive predicted as Negative): 16
- True Negative (Negative): 281
- False Positive (Negative predicted as Positive): 0
- Observation: GradientBoostingClassifier performs the best overall in terms of positive class accuracy, with the fewest false negatives for the positive class. It also has no false positives.

Overall Observations:

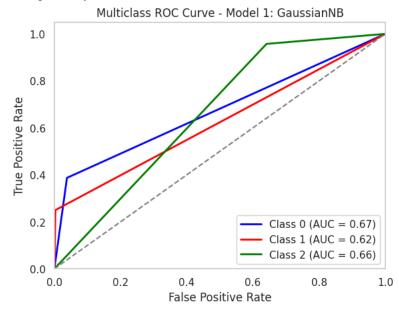

- Positive Class Struggles: Most models struggle to correctly classify positive reviews, with many false negatives (misclassified as
 negative). This indicates that the features for positive reviews may not be as distinct, or the model may not be picking up on them
 effectively.
- Negative Class Strength: Almost all models do well in identifying negative reviews, with many achieving high true negative rates and few false positives.
- 3. Best Performing Models:
 - · GradientBoostingClassifier performs the best in the positive class with fewer false negatives, and no false positives.
 - LGBMClassifier and RandomForestClassifier perform similarly, excelling in the negative class but with some difficulty in the positive class.

Part 10) Model Evaluation

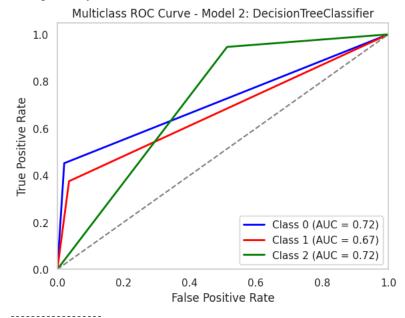

```
# Importing necessary libraries

Model 10: CatBoostClassifier Training Accuracy: 0.9992 Testing Accuracy: 0.9281

- 1. **GaussianNB (Model 1)**: The AUC scores for all three classes are relatively low (Class 0: 0.67, Class 1: 0.62, Class 2: 0.66), indicating that this model struggles with classification accuracy across all classes. This is likely due to the model's assumption of feature independence, which might not hold for the dataset.
- 2. **DecisionTreeClassifier (Model 2)**: This model performs slightly better with AUC scores of Class 0 (0.74) and Class 2 (0.74), but it still struggles with Class 1 (0.62). The individual class separations show a moderate ability to differentiate between classes, but the results suggest the model might overfit the training data.
- 3. **KNeighborsClassifier (Model 3)**: The AUC scores improve to 0.77 for Class 0, 0.68 for Class 1, and 0.74 for Class 2. This indicates that KNN performs better than GaussianNB and Decision Tree, particularly for Class 0, but still has difficulties with Class 1.
- 4. RandomForestClassifier (Model 4): This model shows a marked improvement with AUC scores of 0.93 for Class 0, 0.84 for Class 1, and 0.91 for Class 2. Random Forest provides a strong classification capability and balances well across the classes, making it a strong condidate.
- 5. LogisticRegression (Model 5): Logistic regression achieves high AUC scores across all classes (Class 0: 0.94, Class 1: 0.91, Class 2: 0.92). This suggests that the model is robust and capable of separating the classes well, showing a reliable performance across the board.
- 6. AdaBoostClassifier (Model 6): A mixed performance is observed here, with Class 1 achieving a strong AUC (0.90), but Class 0 and Class 2 have lower AUC scores (0.59 and 0.69, respectively). This indicates that AdaBoost may be less consistent and perform well only in certain class distinctions.
- 7. **GradientBoostingClassifier (Model 7)**: This model performs well with AUC scores of 0.88 for Class 0, 0.90 for Class 1, and 0.88 for Class 2. Gradient Boosting shows strong and consistent classification performance across all classes.
- 8. **XGBClassifier (Model 8)**: With AUC scores of 0.95, 0.97, and 0.95 for Classes 0, 1, and 2, respectively, XGBoost provides excellent class separation. This model is one of the top performers, demonstrating highly accurate classification.
- 9. **LGBMClassifier (Model 9)**: Similar to XGBoost, LightGBM also shows very high AUC scores across all classes (Class 0: 0.95, Class 1: 0.97, Class 2: 0.95), indicating strong performance and reliability.
- 10. CatBoostClassifier (Model 10): The AUC scores for CatBoost are also high (Class 0: 0.91, Class 1: 0.91, Class 2: 0.90). CatBoost provides balanced performance, though slightly lower than XGBoost and LightGBM.

Conclusion:

- Top Performers: XGBoost, LightGBM, and Logistic Regression consistently show the best performance across all classes, with very high
- · Random Forest also shows strong performance, but slightly behind the top three models.
- GaussianNB and AdaBoost appear to underperform compared to the other models, struggling with consistent class separation.

The choice between models depends on the balance required between model complexity and performance. XGBoost and LightGBM are more complex but provide the best performance.
